Abstract: We discuss the problem of event-triggered sliding mode control for a class of uncertain switched systems. First, through the pre-designed sliding mode surface, the corresponding sliding mode dynamics of the switched system are obtained. Second, based on the Lyapunov function technique and average dwell time strategy, the exponential stability of the correlated sliding mode dynamics is analyzed. Then, a sliding mode control law is designed by using the event-triggered mechanism, which can drive the state trajectories of the uncertain switched system to the bounded sliding mode region and maintain it there for subsequent time. Finally, a simulation example is given to verify the effectiveness of the proposed method.

Keywords: event-triggered control; sliding mode control; switched systems; average dwell time; exponential stability

Abbreviations:

$\mathbb{R}$: the set of real numbers; $\mathbb{N}^+$: the set of positive integers; $\mathbb{R}^n$: the real n-dimensional space; $\mathbb{R}^{m \times n}$: the real matrix space; $\|\cdot\|$: the Euclidean norm; $X^T$: the transpose of matrix $X$; $P > 0$: $P$ is positive definite symmetric matrix; $I$: an identity matrix of appropriate dimensions; $*$: an ellipsis for terms induced for symmetry; $\text{rank} (\cdot)$: the rank of a matrix; $\lambda_{\text{max}} (\cdot)$: the maximum eigenvalue of a symmetric matrix; $\lambda_{\text{min}} (\cdot)$: the minimum eigenvalue of a symmetric matrix

1. Introduction

Switched systems belong to an essential class of hybrid dynamical systems, which can be composed of a series of continuous-time or discrete-time dynamic subsystems and switched rules that coordinate the switching between several subsystems. Due to its wide application in different fields
such as flight control systems, underwater vehicle systems, multi-agent vehicle formation planning systems and mechanical systems, it has attracted great attention from researchers [1–7]. Switched signal has a significant influence on the stability analysis of the switched system. For many systems, such as unmanned vehicles and robots, as the operating environment changes, such as road conditions, applied loads and communication structures, the entire system will experience different dynamic characteristics, which can be called switched between different subsystems. With the development of the switched system theory, the stability analysis and control of the switched system have become a research hotspot. Based on the public Lyapunov functional method, zhang et al. propose a robust integral sliding mode control for uncertain switched systems [8]. Fei et al. adopted the average dwell time (ADT) method to study the stability of the switched systems [9].

It is well known that the sliding mode control (SMC) method has strong robustness to the disturbance of unknown boundary and it has the advantages of simple structure, fast response and good transient response. However, in the actual system, there are often external disturbances, modeling errors and other uncertainties, such as input channel interference and external environmental interference. Therefore, the SMC strategy has attracted a lot of attention and has been applied to different systems, including switched systems, fuzzy systems, Markov jump systems and stochastic systems [10–18]. Among them, the main idea of SMC is to utilize a discontinuous control to drive the system state enter into the bounded sliding mode region and keep in there in the subsequent time so that the expected performance such as stability, disturbance suppression and robustness can be achieved.

The design method of SMC is generally divided into two steps: (1) Designing the sliding mode surface function that meets the relevant performance requirements; (2) The approach law method is used to design the sliding mode controller to drive the system state to the sliding mode surface or quasi-sliding mode band. It is worth noting that unlike the design process of SMC for general linear systems, the SMC of switched systems is more complicated due to the presence of switching signals. In [19], a layered SMC scheme for all signals with arbitrary switching is studied. In [20], the SMC problem of a class of continuous-time switched systems with stochastic perturbation was studied. From these studies, it can be found that the SMC of switched systems is mostly carried out in a time-triggered manner, which leads to resource depletion. Therefore, the event-triggered mechanism has been proposed and developed rapidly. In the event-triggered mechanism, only when the sampling point meets the event-triggered conditions, is the transmission carried out. Different from traditional time-triggered control, event-triggered control is more convenient and effective in reducing unnecessary data sampling, which can reduce unnecessary resource waste [21, 22]. Due to the superiority of the event-triggered control in saving resources, the event-triggered control strategy has been gradually applied in many practical systems, such as linear systems [23], nonlinear systems [13, 17, 24, 25], uncertain systems [26, 27] and stochastic systems [28–30].

In addition, there are attempts to combine SMC with the event-triggered mechanism, ensuring the robustness of the system with a smaller event execution time. At present, the event-triggered SMC approach has made great progress. Wu and Gao et al. discussed the strategy of combining the event-triggered scheme with SMC to obtain the stability of the closed-loop system [17]. In [23], a class of event-triggered control schemes for switched systems based on data sampling was considered. Wen et al. studied the event-triggered SMC method for a class of fuzzy systems with induced delay [31]. However, it should be pointed out that the issue of event-triggered control of
Motivated by the above discussions, we aim to solve the SMC problem of uncertain switching systems by an event-triggered mechanism. Unlike most existing results, we propose an event-triggered mechanism by combining the switched properties and reachability of switched sliding mode dynamics. The major contributions of this paper can be listed as follows:

1. The sliding mode control problem of a class of discrete-time uncertain switching systems with matching disturbance is considered, and the purpose of saving resources is realized based on the event-triggered strategy.

2. A linear sliding mode surface is designed. Based on Lyapunov function theory and ADT method, sufficient conditions for the exponential stability of the switching sliding mode dynamics equation are provided.

3. Based on the characteristics of sliding mode control of switching system, a new sliding mode control law is proposed using event triggering mechanisms, and a triggering rule is established to realize the event-triggered sliding mode control of switching system. This reduces the conservative nature of the control strategy.

\section{System description and problem statement}

Consider the following uncertain discrete switched systems with disturbances:

\begin{equation}
\dot{x}(k + 1) = (A_{\sigma(k)} + \Delta A_{\sigma(k)})x(k) + B_{\sigma(k)}u(k) + f_{\sigma(k)}(x(k)),
\end{equation}

where $x(k) \in \mathbb{R}^n$ represents the state, $u(k) \in \mathbb{R}^m$ represents the control input, $\{A_{\sigma(k)}, B_{\sigma(k)} : \sigma \in \mathcal{N}\}$ represents a family of known constant matrices that depends on the index set $\mathcal{N} = \{1, 2, \cdots, N\}$. $\sigma(k): \mathbb{N}^+ \rightarrow \mathcal{N}$ represents the switching signal, which is a piecewise constant function of time $k$.

In addition, $\sigma(k) = i$ means that the $i$th subsystem is activated. For simplicity, we denote

\begin{equation}
A_{\sigma(k)} \triangleq A_i, \quad B_{\sigma(k)} \triangleq B_i, \quad \Delta A_{\sigma(k)} \triangleq \Delta A_i, \quad f_{\sigma(k)}(x(k)) \triangleq f_i(x).
\end{equation}

In this paper, it is assumed that the admissible uncertainty $\Delta A_i, \sigma \in \mathcal{N}$ satisfies $\Delta A_i = E_i M_i(k) H_i$, where $E_i$ and $H_i$ represent known constant matrices, $M_i(k)$ represents an unknown time-varying function matrix satisfying $M_i^T(k) M_i(k) \leq I$. Furthermore, $f_i(k)$ represents the external disturbances function and satisfies $\|f_i(k)\| \leq d_i$, where $d_i > 0$ is a known scalar. Thus, system (2.1) can be rewritten as

\begin{equation}
\dot{x}(k + 1) = (A_i + \Delta A_i)x(k) + B_i(u(k) + f_i(k)).
\end{equation}

\textbf{Assumption 1.} The matrix $B_i$ is full column rank.

\textbf{Lemma 1.} Let $D, H$ be real constant matrix with appropriate dimensions and $G(t)$ satisfies that $G^T(t)G(t) \leq I$. Then, for any $\varepsilon > 0$, we have the following inequality

$$DG(t)H + H^T G^T(t) D^T \leq \varepsilon^{-1}DD^T + \varepsilon H^T H.$$ 

Next, we will give the concepts of ADT and exponential stability of switched systems.

\textbf{Definition 1.} The sliding trajectory of switched system (2.2) is known as in quasi-sliding mode band (QSMB) if there exist positive constant $\delta > 0$ and $\bar{k} > 0$ satisfy $\|s(k)\| \leq \delta$ for any $k > \bar{k}$. In this case, the constant $\delta$ is called a QSMB.
**Definition 2.** For any \( k_2 > k_1 > 0 \), let \( N_{\sigma(k)}(k_1, k_2) \) denote the number of the switching signals of \( \sigma(k) \) over \((k_1, k_2)\). If

\[
N_{\sigma(k)}(k_1, k_2) \leq N_0 + \frac{k_2 - k_1}{T_{\sigma}}
\]

holds for \( T_{\sigma} > 0 \) and \( N_0 \geq 0 \), then, \( T_{\sigma} \) is called an ADT. We choose \( N_0 = 0 \), which is also commonly used in previous literature.

**Definition 3.** [2] The switched sliding mode dynamics (2.1) is said to be exponential stability under the switching signal \( \sigma(k) \), if there are scalar \( \rho > 0 \), \( 0 < \beta < 1 \) such that the state \( x(k) \) of the system satisfies

\[
\|x(k)\| \leq \rho \beta^k \|x(k_0)\|, \quad \forall k \geq k_0.
\]

In this paper, the stability of the sliding mode dynamics is analyzed first. Then, the SMC law is designed to ensure that the state trajectory of the system reaches the specified sliding mode surface in a finite time. For the discrete-time switched system in (2.2), we design the following sliding mode surface function:

\[
s(k) = G_i x(k), \tag{2.3}
\]

where matrix \( G_i \) is chosen so that \( G_iB_i \) is nonsingular.

Obviously, when the system state arrive at the sliding surface (2.3), the ideal sliding surface function satisfies

\[
s(k+1) = s(k) = 0, \tag{2.4}
\]

From (2.3) and (2.4), it can be concluded that

\[
G_i(A_i + \Delta A_i) x(k) + G_i B_i(u(k) + f_i(k)) = 0. \tag{2.5}
\]

From this, the equivalent control can be obtained as

\[
u_{eq}(k) = -(G_iB_i)^{-1} G_i(A_i + \Delta A_i) x(k) - f_i(k). \tag{2.6}
\]

Substituting (2.6) into (2.2) yields

\[
x(k+1) = (I - B_i(G_iB_i)^{-1} G_i)(A_i + \Delta A_i) x(k). \tag{2.7}
\]

3. Exponential stability analysis

In this section, we use the ADT method to analyze the exponential stability of sliding mode dynamics (2.7).

**Theorem 1.** Consider the discrete-time switched system (2.1) with a sliding mode surface as shown in (2.3) and the system satisfies Assumption 1. For any scalar \( 0 < \gamma < 1 \), if the parameters \( \varepsilon_{i1} > 0, \varepsilon_{i2} > 0 \), \( i \in N \) and matrix \( P_i > 0 \) exist, satisfying the following linear matrix inequalities (LMIs):

\[
\begin{bmatrix}
\theta_{i1} & \theta_{i2} \\
* & -\varepsilon_{i1} I
\end{bmatrix} < 0, \tag{3.1}
\]

\[
\begin{bmatrix}
-P_i & \theta_{i3} \\
* & -\varepsilon_{i2} I
\end{bmatrix} < 0. \tag{3.2}
\]
where

\[ \theta_1 = \left[(I - B_i(G_iB_i)^{-1}G_i)A_i\right]^T P_i (I - B_i(G_iB_i)^{-1}G_i) A_i + \varepsilon_{i_1} H_i^T H + \varepsilon_{i_2} H_i^T H - \gamma P_i, \]
\[ \theta_2 = \left[(I - B_i(G_iB_i)^{-1}G_i)A_i\right]^T P_i (I - B_i(G_iB_i)^{-1}G_i) E_i, \]
\[ \theta_3 = P_i (I - B_i(G_iB_i)^{-1}G_i) E_i. \]

Then, with the parameter

\[ \mu = \max_{i,j \in N,i \neq j} \frac{\lambda_{\max}(P_i)}{\lambda_{\min}(P_j)} \] (3.3)

and the average dwell time \( T_\sigma \) satisfies

\[ T_\sigma \geq T_\sigma^* > -\frac{\ln \mu}{\ln \gamma}, \] (3.4)

the system (2.7) is exponential stability. Furthermore, the state is estimated by

\[ \|x(k)\| \leq \rho \beta^{k-k_0} \|x(0)\| \] (3.5)

and the parameters satisfy

\[ a = \min_{i \in N} \lambda_{\min}(P_i), \quad b = \max_{i \in N} \lambda_{\max}(P_i), \]
\[ \beta = \sqrt{\gamma \mu T}, \quad \rho = \frac{b}{a} \geq 1. \] (3.6)

Proof. For system (2.7), construct the following Lyapunov function

\[ V_i(k) = x^T(k) P_i x(k), \] (3.7)

where \( P_i \) is the positive-definite matrix to be determined later. From Eq (2.7), we obtain

\[ V_i(k+1) - \gamma V_i(k) \]
\[ = x^T(k) \left[(I - B_i(G_iB_i)^{-1}G_i) (A_i + \Delta A_i)\right] P_i \left[(I - B_i(G_iB_i)^{-1}G_i) \right. \]
\[ \times (A_i + \Delta A_i) x(k) - \gamma x^T(k) P_i x(k) \]
\[ = x^T(k) \left[(I - B_i(G_iB_i)^{-1}G_i) A_i\right] P_i \left[(I - B_i(G_iB_i)^{-1}G_i) A_i x(k) \right. \]
\[ + x^T(k) \left[(I - B_i(G_iB_i)^{-1}G_i) \Delta A_i\right] P_i \left[(I - B_i(G_iB_i)^{-1}G_i) A_i x(k) \right. \]
\[ + x^T(k) \left[(I - B_i(G_iB_i)^{-1}G_i) A_i\right] P_i \left[(I - B_i(G_iB_i)^{-1}G_i) \Delta A_i x(k) \right. \]
\[ + x^T(k) \left[(I - B_i(G_iB_i)^{-1}G_i) \Delta A_i\right] P_i \left[(I - B_i(G_iB_i)^{-1}G_i) \Delta A_i x(k) \right. \]
\[ \leq x^T(k) \left[(I - B_i(G_iB_i)^{-1}G_i) A_i\right] P_i \left[(I - B_i(G_iB_i)^{-1}G_i) A_i x(k) \right. \]
\[ + \varepsilon_{i_1} x^T(k) H_i^T H_i x(k) + \varepsilon_{i_2} x^T(k) \left[(I - B_i(G_iB_i)^{-1}G_i) A_i\right] P_i \]
\[ \times \left[(I - B_i(G_iB_i)^{-1}G_i) E_i P_i \left[(I - B_i(G_iB_i)^{-1}G_i) E_i\right]\right]. \]
\[
\times \left( I - B_i (G_i B_i)^{-1} G_i \right) A_i x(k) + x^T(k) \left[ \left( I - B_i (G_i B_i)^{-1} G_i \right) \Delta A_i \right]^T \\
\times P_i \left( I - B_i (G_i B_i)^{-1} G_i \right) \Delta A_i x(k) - \gamma x^T(k) P_i x(k) .
\] (3.8)

From (3.8) and Schur’s complement lemma, we know that

\[
V_i(k+1) - \gamma V_i(k) < 0.
\] (3.9)

We only have to do is

\[
\begin{bmatrix}
\theta_{i4} & \theta_{i2} & \theta_{i5} \\
* & -\epsilon_{i1} I & 0 \\
* & * & -P_i
\end{bmatrix} < 0,
\] (3.10)

where

\[
\theta_{i4} = \left( I - B_i (G_i B_i)^{-1} G_i \right) A_i^T P_i \left( I - B_i (G_i B_i)^{-1} G_i \right) A_i + \epsilon_{i1} H_i^T H_i - \gamma P,
\]

\[
\theta_{i2} = \left( I - B_i (G_i B_i)^{-1} G_i \right) A_i^T P_i \left( I - B_i (G_i B_i)^{-1} G_i \right) E_i,
\]

\[
\theta_{i5} = \left( I - B_i (G_i B_i)^{-1} G_i \right) \Delta A_i^T P_i.
\]

From (3.10), it can be concluded that

\[
\begin{bmatrix}
\theta_{i4} & \theta_{i2} & 0 \\
* & -\epsilon_{i1} I & 0 \\
* & * & -P_i
\end{bmatrix} + \theta \tilde{N} \Pi + \Pi^T \tilde{N}^T \theta^T < 0,
\] (3.11)

where

\[
\theta = \begin{bmatrix} H_i & 0 & 0 \end{bmatrix}^T, \quad \tilde{N} = M^T(k),
\]

\[
\Pi = \begin{bmatrix} 0 & 0 & \left( I - B_i (G_i B_i)^{-1} G_i \right) E_i^T P_i \end{bmatrix}.
\]

From Eqs (3.1) and (3.2) and Schur’s complement, (3.11) can be obtained. It can be shown from (3.11) that

\[
V_i(k+1) \leq \gamma V_i(k).
\] (3.12)

Therefore, for any \( k \in [k_l, k_{l+1}) \), it can be derived by (3.12)

\[
V_{\sigma(k)}(k) \leq \gamma^{k-k_l} V_{\sigma(k_l)}(k_l).
\] (3.13)

According to (3.3) and (3.13), the following inequation

\[
V_{\sigma(k)}(k) \leq \gamma^{k-k_l} \mu V_{\sigma(k_{l-1})}(k_l) \leq \cdots \\
\leq \gamma^{k-k_{l-1}} \mu^l V_{\sigma(k_{l-1})}(k_l) \leq \gamma \mu^{l-1} V_{\sigma(k_{l-1})}(k_l) \leq \gamma \mu^{l-1} \mu V_{\sigma(k_0)}(k_l) \leq \gamma \mu^{l-1} \mu V_{\sigma(k_0)}(k_0)
\] (3.14)

holds.
Considering (3.6), we have
\[ a\|x(k)\|_2^2 \leq V_{\sigma(k)}(k) \] (3.15)
and
\[ V_{\sigma(k)}(k_0) \leq b\|x(k_0)\|_2^2. \] (3.16)

By (11)
\[ \gamma \mu \frac{1}{\mu} \leq \gamma \frac{\ln \mu}{\ln \gamma} \leq 1. \] (3.17)

Combining (3.14)–(3.17), we yield
\[ \|x(k)\|_2 \leq \frac{1}{a} V_{\sigma(k)}(k) \leq \frac{b}{a} \beta^{2(k-k_0)} \|x(k_0)\|_2^2. \] (3.18)

Then (2.7) is exponential stability. □

4. Event-triggered SMC law analysis

Next, an event-triggered SMC law is designed to ensure the reachability of the state trajectories of the switching system in a finite time. To realize the control objectives, the following reaching law approach is considered for the system in Eq (2.2):
\[ s(k+1) - s(k) = -r_i \text{sgn}(s(k)) + \tilde{f}(i, x, k), \quad i \in \mathcal{N}, \] (4.1)
where
\[ \tilde{f}(i, x, k) = G_i B_i f_i(k), \quad \|\tilde{f}(i, x, k)\| \leq \tilde{f}_d, \]
\[ r_i \] is the given switching gain scalar. Based on the sliding mode surface (2.3) and the switched system (2.2), as well as the constant reaching law (4.1), the following SMC law can be obtained:
\[ u(k) = -(G_i B_i)^{-1} \{ G_i (A_i - I)x(k) + r_i \text{sgn}(s(k)) \} - \tilde{u}(k), \] (4.2)
where
\[ \tilde{u}(k) = (G_i B_i)^{-1} G_i \Delta A_i x(k). \]

Since the controller (4.2) contains the uncertain \( \tilde{u}(k) \), it is not suitable for practical. Therefore, the SMC law is recommended to be formulated as
\[ u(k) = -(G_i B_i)^{-1} \{ G_i (A_i - I)x(k) + r_i \text{sgn}(s(k)) \} - \hat{u}(k), \] (4.3)
where
\[ \hat{u}(k) = \begin{cases} \left( (G_i B_i)^{-1} [G_i E_i] \|H_i x(k)\| + (G_i B_i) \|G_i B_i\| \eta_1 \right) \frac{x(k)}{\|x(k)\|}, & \text{if } \|s(k)\| \neq 0, \\ 0, & \text{if } \|s(k)\| = 0, \end{cases} \]
and \( \eta_1 \) is a positive scalar.

Since \( G_i B_i \) is invertible, the SMC law (4.2) can be easily obtained from the above equation.

On the result above, the event-triggered sliding mode controller design method will be developed.

Assuming that \( \{s_l, l \in \mathbb{N}, s_0 = 0\} \) is a triggering sequence generated by an event-triggered scheme.
Therefore, the sliding mode controller will be updated at every $s_i$ instant and remain unchanged until the next triggered instant $s_{i+1}$. Define the state error as

$$e(k) \triangleq x(k) - x(s_i)$$

for all $k \in [s_i, s_{i+1})$ and the sliding surface function based on event-triggered scheme can be represented as

$$s(k) = G_i x(s_i), \ i \in N. \quad (4.4)$$

Moreover, the following event-triggered sliding mode controller can be obtained as

$$u(k) = -(G_iB_i)^{-1} \left\{ G_i(A_i - I)x(s_i) + r_i \text{sgn}(s_i) \right\} - \hat{u}(s_i), \ k \in [s_i, s_{i+1}). \quad (4.5)$$

Then, the following theorem is given to ensure the effectiveness of the event-triggered sliding mode controller in (4.5).

**Theorem 2.** Considering the switched system (2.2), sliding surface function (2.3) and event-triggered SMC law (4.5), we assume that the event-triggered SMC law (4.2) is updated at the triggered instants $\{s_i\}_{i \in \mathbb{N}}$. For a given parameter $v_i > 0$ and the switching gain $r_i > v_i + f_{id} + \eta_i$, if the following equation

$$\|G_i\| \cdot \|A_i\| \cdot \|e(k)\| \leq v_i, \ i \in N \quad (4.6)$$

holds for all $k$. Then, the state trajectory of the switched system (2.2) under the event-triggered SMC law (4.5) converges to the sliding mode surface (2.3) in a finite time and maintains it there all the time. Further, the practical QSMB is expressed as

$$\delta = \max_{i \in N} \delta_i, \quad (4.7)$$

where

$$\delta_i = \max \left\{ \sqrt{\psi_i^2 + 2\zeta_i \psi_i v_i \|A_i\|^{-1}} \right\},$$

$$\zeta_i = r_i - v_i - f_{id} - \eta_i, \quad \psi_i = \frac{(r_i + v_i + f_{id} + \eta_i)^2}{2(r_i - v_i - f_{id} - \eta_i)}.$$ 

**Proof.** From the switched system (2.2) and the sliding mode surface function(2.3), we have

$$\Delta s(k) = s(k + 1) - s(s_i)$$

$$= G_i x(k + 1) - G_i x(s_i)$$

$$= G_i (A_i + \Delta A_i) x(k) + G_i B_i \left[ u(k) + f_i(k) \right] - G_i x(s_i).$$

From (4.5), we obtain

$$\Delta s(k) = G_i (A_i + \Delta A_i) x(k) + G_i B_i \left[ u(k) + f_i(k) \right] - G_i x(s_i)$$

$$= G_i A_i x(k) + G_i \Delta A_i x(k) - G_i (A_i - I) x(s_i) - r_i \text{sgn}(s_i)$$

$$- G_i B_i \hat{u}(s_i) + G_i B_i f_i(k) - G_i x(s_i)$$

$$= G_i A_i x(k) + G_i \Delta A_i x(k) - G_i A_i x(s_i) + G_i x(s_i) - r_i \text{sgn}(s_i)$$

$$- G_i B_i \hat{u}(s_i) + G_i B_i f_i(k) - G_i x(s_i)$$

$$= \sum_{i \in N} \max_{s_i} \delta_i,$$
Therefore, according to (4.8), it can be concluded

\[ \Delta V_s(k) = s^T(k) \Delta s(k) + \frac{1}{2} \Delta s^T(k) \Delta s(k) \]

\[ = s^T(k) \left[ G_i A_i e(k) + G_i B_i (\hat{u}(s_i) - \hat{u}(s_i)) - r_i sgn(s_i) + \bar{f}(s, x, k) \right] \]

\[ + \frac{1}{2} \left[ G_i A_i e(k) + G_i B_i (\hat{u}(s_i) - \hat{u}(s_i)) - r_i sgn(s_i) + \bar{f}(s, x, k) \right]^T \]

\[ \times \left[ G_i A_i e(k) + G_i B_i (\hat{u}(s_i) - \hat{u}(s_i)) - r_i sgn(s_i) + \bar{f}(s, x, k) \right] \]

\[ = s^T(k) \left[ G_i A_i e(k) + G_i B_i (\hat{u}(s_i) - \hat{u}(s_i)) - r_i sgn(s_i) + \bar{f}(s, x, k) \right] \]

\[ + \frac{1}{2} \left[ G_i A_i e(k) - r_i sgn(s_i) \right]^T \left[ G_i A_i e(k) - r_i sgn(s_i) \right] + \bar{f}^2(s, x, k) \]

\[ + [G_i B_i (\hat{u}(s_i) - \hat{u}(s_i))]^T [G_i B_i (\hat{u}(s_i) - \hat{u}(s_i))] \]

\[ + \frac{1}{2} \left[ 2 [G_i A_i e(k) - r_i sgn(s_i)] \times \bar{f}(s, x, k) + 2 [G_i A_i e(k) - r_i sgn(s_i)] \times \bar{f}(s, x, k) \right]. \]
Therefore, it can be concluded from (4.10) that when \(|s(k)| > \psi_i\), \(\Delta V_s(k) < 0\) can be obtained by selecting \(r_i = v_i + \hat{f}_{id} + \eta_i\), ensuring the reachability of sliding mode dynamics in a finite time.

However, if \(|s(k)| \leq \psi_i\), \(\Delta V_s(k) < 0\) cannot be guaranteed, but it can be determined that the trajectory of the sliding function \(s(k)\) is bounded. Next, we calculate the value of the sliding surface function at the next time instant \(s(k+1)\), according to \(|s(k)| \leq \psi_i\) and (4.10), we have

\[
\|s(k+1)\| \leq \sqrt{\|s(k)\|^2 - 2\zeta_i \{\|s(k)\| - \psi_i\}} \\
\leq \sqrt{\|s(k)\|^2 + 2\zeta_i \psi_i} \\
\leq \psi_i^2 + 2\zeta_i \psi_i.
\]

Then, the maximum deviation of the \(s(k)\) can be calculated as

\[
\|s(k) - s(s_l)\| = \|G_i e(k)\| \leq \|G_i\| \cdot \|e(k)\| \leq v_i \|A_i\|^{-1}.
\]

In summary, we obtain the QSMB in (4.7), which completes the proof. □

Based on the above research, the stability of the switched system (2.2) with external disturbances can be guaranteed by designing the event-triggered SMC law (4.5). According to the condition (4.6), the next event trigger time \(s_{l+1}\) can be determined as follows:

\[
s_{l+1} = \inf \left\{k > s_l \|G_i\| \cdot \|A_i\| \cdot \|e(k)\| > v_i \right\}.
\]

Thus, we can obtain the sequence of triggering instants \(\{s_l, l \in \mathbb{N}, s_0 = 0\}\) for the SMC law (4.5). In addition, it can be seen from (4.11) that for triggering conditions, there is always an interval between events, so Zeno phenomenon is excluded.

In particular, the triggering condition is established based on the reachability of the switched SMC system, which reduces conservative of the switched system.

5. Simulation example

Consider the switched system (2.1), which has two modes and parameters as follows.

Subsystem 1:

\[
A_1 = \begin{bmatrix} 0.3 & -0.4 \\ -0.1 & -0.2 \end{bmatrix}, \quad B_1 = \begin{bmatrix} -0.1 \\ -0.12 \end{bmatrix}, \quad E_1 = \begin{bmatrix} 0.1 \\ 0.2 \end{bmatrix}, \quad M_1(k) = \cos(0.3k),
\]

\[
H_1 = \begin{bmatrix} 0.2 \\ 0.1 \end{bmatrix}, \quad f_1(k) = 0.5 \sqrt{x_1^2(k) + x_2^2(k)}.
\]

Subsystem 2:

\[
A_2 = \begin{bmatrix} 0.1 & -0.3 \\ -0.1 & -0.2 \end{bmatrix}, \quad B_2 = \begin{bmatrix} -0.4 \\ 0.2 \end{bmatrix}, \quad E_2 = \begin{bmatrix} 0.3 \\ -0.5 \end{bmatrix}, \quad M_2(k) = \sin(2k),
\]

\[
H_2 = \begin{bmatrix} 0.1 \\ 0.2 \end{bmatrix}, \quad f_2(k) = 0.3 \sqrt{x_1^2(k) + x_2^2(k)}.
\]
Select $G_1 = G_2 = \begin{bmatrix} -3.9002 & 0.6240 \end{bmatrix}$ and scalar $\gamma = 0.9$, solving LMIs (3.1) and (3.2) yields

$$
\varepsilon_{11} = 136.2037, \quad \varepsilon_{12} = 135.9712, \quad \varepsilon_{21} = 114.5577, \quad \varepsilon_{22} = 109.8347,$$

$$
P_1 = \begin{bmatrix} 201.5647 & -0.3130 \\ -0.3130 & 199.6581 \end{bmatrix}, \quad P_2 = \begin{bmatrix} 122.6677 & -1.8653 \\ -1.8653 & 111.3075 \end{bmatrix}.
$$

Therefore, the event-triggered sliding surface function (4.4) can be expressed by

$$
S(t) = \begin{bmatrix} -3.9002 & 0.6240 \end{bmatrix} x(s_i).
$$

According to Theorem 1, the parameters $\mu$ and $T_\sigma$ are designed as follows:

$$
\mu = \max_{i,j \in N, i \neq j} \frac{\lambda_{\text{max}}(P_i)}{\lambda_{\text{min}}(P_j)}, \quad T_\sigma > T_\sigma^* > -\frac{\ln \mu}{\ln \gamma}.
$$

Therefore, it can be concluded

$$
\mu = 1.1678, \quad T_\sigma = 1.5.
$$

Select the event-triggered parameters as $v_1 = v_2 = 0.05$. According to (4.11), the triggering instants $s_i$ is determined by

$$
s_i = \begin{cases} 
\inf \{ k > s_{i-1} \mid \| e(k) \| > 0.05 \}, & i = 1, \\
\inf \{ k > s_{i-1} \mid \| e(k) \| > 0.05 \}, & i = 2.
\end{cases}
$$

Select the parameter $\eta_1 = \eta_2 = 0.8$, we get

$$
\bar{f}_{1d} = 0.1576, \quad \bar{f}_{2d} = 0.3370,
$$

$$
r_1 = 0.04 + v_1 + f_{1d} + \eta_1 = 1.0476,
$$

$$
r_2 = 0.06 + v_2 + f_{2d} + \eta_2 = 1.2470.
$$

Therefore, the event-triggered SMC law can be calculated as

$$
u(k) = \begin{cases} 
\begin{bmatrix} -8.4653 & -2.5743 \end{bmatrix} x(s_i) - 3.3242 \sgn(S(s_i)), & if \ i = 1 and \| S(s_i) \| = 0, \\
\begin{bmatrix} -2.0463 & -0.2500 \end{bmatrix} x(s_i) - 0.7401 \sgn(S(s_i)), & if \ i = 2 and \| S(s_i) \| = 0, \\
-8.4653 \times \left\| \begin{bmatrix} 0 & 0.2 \\ 0.2 & 0 \end{bmatrix} x(s_i) \right\| + 8.0553 \frac{S(s_i)}{\| S(s_i) \|}, & if \ i = 1 and \| S(s_i) \| \neq 0, \\
-2.0463 \times \left\| \begin{bmatrix} 0 & 0.2 \\ 0.2 & 0 \end{bmatrix} x(s_i) \right\| + 0.2818 \frac{S(s_i)}{\| S(s_i) \|}, & if \ i = 2 and \| S(s_i) \| \neq 0.
\end{cases}
$$
To reduce the chattering phenomenon, the sign function \( \text{sgn}(S(k)) \) is replaced by \( \frac{S(k)}{||S(k)||+0.1} \). For the initial state

\[
x(0) = \begin{bmatrix} 3 & -1 \end{bmatrix}^T,
\]

the switched signal is shown in Figure 1. Figure 2 shows the trigger instants and intervals of the event-triggered mechanism. It can be seen that the event-triggered scheme can reduce the number of control task execution. Figure 3 shows the state trajectory of the system, indicating that asymptotically converges to zero in a finite time. Figure 4 describes the event-triggered sliding surface and the event-triggered SMC law is shown in Figure 5.

6. Conclusions

In this paper, we have investigated the problem of the event-triggered SMC for a class of discrete-time switched systems. Based on the Lyapunov function technique and the ADT strategy, the exponential stability of the correlated sliding mode dynamics is analyzed by linear matrix inequalities. In addition, the event-triggered SMC law is designed using the event-triggered mechanism, which can guarantee that the state trajectory of the system reaches the bounded sliding mode region in a finite time. Furthermore, a sequence of triggering instants are generated by establishing triggering conditions, which can effectively improve the execution efficiency of control tasks. However, chattering decrease is a challenge problem of sliding mode control, and the gain scheduling using fuzzy rules is an effective approach [32]. These may be further considered in the future research.
