Abstract: Reversible codes have a range of wide applications in cryptography, data storage, and communication systems. In this paper, we investigated reversible codes under the Rosenbloom-Tsfasman metric (RT-metric). First, some properties of reversible codes in the RT-metric were described. An essential condition for a reversible code to be a maximum distance separable code (MDS code, in short) in the RT-metric was established. A necessary condition for a binary self-dual code to be reversible was proven and the same was generalized for \(q\)-ary self-dual reversible codes. Several constructions for reversible RT-metric codes were provided in terms of their generator matrices.

Keywords: self-dual code; reversible code; MDS code; linear code; RT-metric

Mathematics Subject Classification: 94B05

1. Introduction

Massey [1] introduced reversible codes that are known to exhibit useful properties in certain retrieval systems and data storage. Moreover, some reversible codes have been proven to possess excellent solid burst error correction capability and high transmission efficiency [2, 3]. It has also recently been observed that reversible codes have broad applications in various areas of mathematics, including cryptography [4, 5], and the theory of DNA codes [6–8].

Interestingly, the class of reversible codes is closely connected to that of BCH codes because it is an important subclass of BCH codes. It is also closely related to the class of linear complementary dual codes (LCD codes, in short) introduced by Massey in [9]. In fact, Yang and Massey proved that a cyclic code is a reversible code if and only if it is an LCD code [10]. This interconnection between reversible codes, BCH codes, and LCD codes adds to their importance and potential applications in various domains.

The Rosenbloom-Tsfasman metric, also known as the RT-metric, was first introduced by
Rosenbloom and Tsfasman [11] in the field of coding theory. It was later introduced into the theory of uniform distributions by Skriganov [12] and Martin and Stinson [13]. RT-metric is a generalization of the classical Hamming metric, and it has immediately attracted the attention of many coding theorists, resulting in extensive research on codes equipped with this metric. The majority of research on codes in this metric focuses on various bounds [14], linearity [15–17], weight distribution and MacWilliam’s identities [18–21], groups of automorphisms [22], maximum distance separability [23], burst error enumeration [24–26], normality [27], covering properties [28], construction of self-dual codes [29], and existence of LCD codes [30] over various algebraic structures.

In the context of coding theory [11] and its corresponding notion in uniform distributions [12], the goal is to construct an RT-metric code with codewords that are maximally distant from each other, aiming for the smallest RT-distance between any two codewords to be as large as possible. Additionally, there is a desire for the RT-metric code to be as large as possible, akin to codes in the classical Hamming metric. However, these two objectives often conflict. Therefore, the aim is to achieve the maximum number of codewords with the greatest possible minimum distance or the largest minimum distance for a given number of codewords. Codes meeting these criteria are termed maximum distance separable (MDS) codes. Rosenbloom and Tsfasman [11] initially defined MDS codes over $\mathbb{F}_q$ with the $\rho$-metric in relation to potential information theoretic applications. Furthering their theory, Skriganov [12] related these codes to uniform distributions. An $[n,k,d_\rho]_q$ code in the RT-metric that attains the Singleton bound is considered an MDS code, meaning $d_\rho = n - k + 1$. Marka and Selvaraj [31] demonstrated that optimal codes in $\mathbb{F}_n^q$ are MDS, and vice versa.

As a result of this intriguing distinction of MDS codes in the RT metric, there arises a significant need for comprehensive study of MDS codes in this metric, such as the existence of MDS reversible codes. This paper aims to address this specific problem by investigating the presence of MDS reversible codes and subsequently exploring their properties if they are found to exist.

2. Preliminaries

Let $u = (u_1, u_2, \ldots, u_n)$ and $v = (v_1, v_2, \ldots, v_n)$ be any two vectors in $\mathbb{F}_q^n$. The $\rho$-distance or RT-distance between them is denoted by $d_\rho(u, v)$, defined as $d_\rho(u, v) = \max\{|i|u_i \neq v_i, 1 \leq i \leq n\}$. A $q$-ary RT-metric code of length $n$ refers to a subset of the space $\mathbb{F}_q^n$ equipped with this metric. If this subset is a subspace, it is referred to as a linear RT-metric code. A generator matrix $G$ of a $k$-dimensional linear code $C$ in $\mathbb{F}_q^n$ is a $k \times n$ matrix such that its rows form a basis for $C$. The coordinates of any set of $k$ linearly independent columns of $G$ represent the information set for code $C$.

To derive MacWilliam’s type relations for codes in the RT-metric, an essential inner product was introduced in [19] on the matrix space $\text{Mat}_{m \times n}(\mathbb{F}_q)$. This particular inner product holds great importance in the investigation of codes in the RT-metric, as it influences various intriguing results. For instance, it indicates that the dual of an MDS code, under this specific inner product will also be an MDS code, which represents one of the noteworthy results in this context.

For $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_n), \beta = (\beta_1, \beta_2, \ldots, \beta_n) \in \mathbb{F}_q^n$, the inner product of $\alpha$ and $\beta$ is given by

$$\langle \alpha, \beta \rangle = \langle \beta, \alpha \rangle = \sum_{i=1}^{n} \alpha_i \beta_{n-i+1}.$$ 

Then, the dual $C^\perp$ of the code $C$ can be defined as
\( \mathcal{C}^\perp = \{ \alpha \in \mathbb{F}_q^n | \langle \alpha, \beta \rangle = 0 \text{ for all } \beta \in \mathcal{C} \} \).

An RT-metric code \( \mathcal{C} \) is categorized based on certain properties. If \( \mathcal{C} \) is contained within its dual code \( \mathcal{C}^\perp \), it is referred to as self-orthogonal. A self-dual code, on the other hand, satisfies the condition \( \mathcal{C} = \mathcal{C}^\perp \). In contrast, for a code to be LCD, there are no non-zero codewords in common between \( \mathcal{C} \) and its dual \( \mathcal{C}^\perp \). \( \mathcal{C} \) is termed reversible if for every codeword \( c = (v_1, v_2, \ldots, v_n) \) in \( \mathcal{C} \), its reverse \( \text{Flip}(c) = (v_n, v_{n-1}, \ldots, v_2, v_1) \) is also an element of \( \mathcal{C} \) and \( c \) is self-reversible if \( c = \text{Flip}(c) \).

2.1. Notations

Let \( \mathcal{P} = (p_{ij})_{m \times n} \) be a matrix of size \( m \times n \). Then, we use the following notation (see Table 1) throughout this study.

**Table 1.** Notations and abbreviations.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( I_n )</td>
<td>the identity matrix of degree ( n )</td>
</tr>
<tr>
<td>( R_n )</td>
<td>a matrix ((r_{ij})<em>{n \times n}), where ( r</em>{ij} = 1 ), if ( i + j = n + 1 ) and ( r_{ij} = 0 ) otherwise</td>
</tr>
<tr>
<td>( \mathcal{P}^T )</td>
<td>the transpose of a matrix ( \mathcal{P} ), given by ( \mathcal{P}^T = (p_{ji})_{n \times m} )</td>
</tr>
<tr>
<td>( \text{Flip}(\mathcal{P}) )</td>
<td>the column-reversed matrix of a matrix ( \mathcal{P} ), given by ( \text{Flip}(\mathcal{P}) = (p_{i,n-j+1})_{m \times n} )</td>
</tr>
<tr>
<td>( R_k \mathcal{P} )</td>
<td>the row-reversed matrix of a rectangle matrix ( \mathcal{P} )</td>
</tr>
<tr>
<td>( \mathcal{P}^S )</td>
<td>the flip-diagonal transpose of a matrix ( \mathcal{P} ), which transposes the flip of ( \mathcal{P} ) across its diagonal, i.e., ( \mathcal{P}^S = (p_{m-i+1,n-j+1})_{m \times n} )</td>
</tr>
<tr>
<td>( \mathcal{P}_k )</td>
<td>( k \times k ) square matrix</td>
</tr>
<tr>
<td>( \text{RMDS} )</td>
<td>reversible MDS</td>
</tr>
<tr>
<td>( \text{SR} )</td>
<td>self-dual reversible</td>
</tr>
<tr>
<td>( \text{SR} - \text{MDS} )</td>
<td>self-dual reversible MDS</td>
</tr>
<tr>
<td>([x])</td>
<td>it rounds ( x ) up to the nearest integer</td>
</tr>
</tbody>
</table>

Let \( \mathcal{P} \) and \( \mathcal{Q} \) be square matrices of order \( n \). If \( \mathcal{P} \mathcal{P}^T = I_n = \mathcal{P}^T \mathcal{P} \), then \( \mathcal{P} \) is called orthogonal. If \( \mathcal{P} = \mathcal{P}^T \), then \( \mathcal{P} \) is called symmetric. \( \mathcal{P} \) is called centrosymmetric if \( \mathcal{P} = \mathcal{P}^S \). Furthermore, the following properties are straightforward:

- \( R_n = \text{Flip}(I_n) \);
- \( R_n^T = R_n^S = R_n \);
- \( R_n^S = I_n \);
- \( \mathcal{P}^S = R_n \mathcal{P} R_n \);
- \( (\mathcal{P}^T)^S = (\mathcal{P}^S)^T \);
- \( (\mathcal{P}^S)^S = \mathcal{P} \);
- \( (\mathcal{P} + \mathcal{Q})^S = \mathcal{P}^S + \mathcal{Q}^S \);
- \( (\mathcal{P} \mathcal{Q})^S = \mathcal{Q}^S \mathcal{P}^S \);
- \( \text{Flip}(\mathcal{P}) = \mathcal{P} R_n \).

3. Some properties of reversible codes

**Lemma 3.1.** If \( \mathcal{C} \) is a reversible code of length \( n \) with dimension \( k \) over \( \mathbb{F}_q \) with generator matrix \( G \), then \( G^S \) is also a generator matrix of \( \mathcal{C} \).
Proof. Consider $\mathcal{C}$ as a reversible code with generator matrix $G$. Since $\mathcal{C}$ is reversible, $\text{Flip}(G)$ is also a generator matrix of $\mathcal{C}$. If $R_k$ is non-singular, then $G^S = R_k \text{Flip}(G)$ is also a generator matrix of $\mathcal{C}$. Thus, the lemma holds true.

**Theorem 3.1.** Let $\mathcal{C}$ be a linear code of even length $n$ over $\mathbb{F}_q$ with a generator matrix in the form $G = [A|A^S]$. Then, $\mathcal{C}$ is reversible.

**Proof.** The proof is similar to that of Theorem 3.1.

$G = [A|A^S]$ is a generator matrix of $\mathcal{C} \iff \text{Flip}(G) = [\text{Flip}(A^S) | \text{Flip}(A)]$

$\iff R_k \text{Flip}(G) = R_k [\text{Flip}(A^S) | \text{Flip}(A)]$

$\iff G^S = [(A^S)^S | A^S]$

$\iff G^S = [A|A^S]$

$\iff G^S = G.$

Suppose $\mathcal{C}$ is not reversible. Then, $\text{Flip}(G)$ cannot be a generator matrix of $\mathcal{C}$. However, as $R_k$ is non-singular, it implies that $G^S = R_k \text{Flip}(G)$ is also not a generator matrix of $\mathcal{C}$, leading to a contradiction. Therefore, $\mathcal{C}$ must be reversible.

**Theorem 3.2.** Let $\mathcal{C}$ be a linear code of odd length $n$ over $\mathbb{F}_q$, with a generator matrix $G$ in the form $G = [A|yA^S]$, where $y$ is a column vector such that $y = y^S$. Then, $\mathcal{C}$ is reversible.

**Proof.** The proof is similar to that of Theorem 3.1.

(i) If $\mathcal{C}$ has an odd length $n$, then we can express a generator matrix of $\mathcal{C}$ in the form $G = [A|yA^S]$, where $y$ is a column vector such that $y = y^S$ if and only if the total number of self-reversible codewords in code $\mathcal{C}$ is $q^{\frac{k+1}{2}}$.

(ii) If $\mathcal{C}$ has an even length $n$, then we can represent a generator matrix of $\mathcal{C}$ in the form $G = [A|yA^S]$ if and only if the total number of self-reversible codewords in $\mathcal{C}$ is $q^{\frac{k+1}{2}}$.

**Proof.** Let $\mathcal{C}$ be a reversible code of length $n$ with dimension $k$ over $\mathbb{F}_q^n$.

(i) Let us assume that $G = [A|yA^S]$ represents a generator matrix for a reversible code $\mathcal{C}$ with an odd length $n$, where $A$ is a matrix and $y$ is a column vector satisfying $y = y^S$.

Case A: Assume $k$ is even. Then, no self-reversible codeword exists as a row of generator matrix $G = [A|yA^S]$. Therefore, $r_i = \text{Flip}(r_{k-i+1})$, $\forall i \in \{1, 2, \ldots, k\}$, where $r_i$ is the $i^{th}$ row of $G$. Since $\mathcal{C}$ is reversible, $c_i = r_i + r_{k-i+1}$ ($i = 1, 2, \ldots, \frac{k}{2}$) are distinct self-reversible codewords. All distinct self-reversible codewords thus form a subspace of dimension $\frac{k}{2}$ of $\mathcal{C}$, leading to a total of $q^{\frac{k}{2}}$ self-reversible codewords.

Case B: Assume $k$ is odd. Then, exactly one self-reversible codeword exists as a row of generator matrix $G = [A|yA^S]$ which is the $\left(\frac{k+1}{2}\right)^{th}$ row of $G$. Therefore, $r_i = \text{Flip}(r_{k-i+1})$, $\forall i \in \{1, 2, \ldots, \frac{k-1}{2}\}$, where $r_i$ is the $i^{th}$ row of $G$. Since $\mathcal{C}$ is reversible, $c_i = r_i + r_{k-i+1}$ ($i = 1, 2, \ldots, \frac{k-1}{2}$) and the $\left(\frac{k+1}{2}\right)^{th}$ row vectors as self-reversible codewords in $G$ are $\frac{k+1}{2}$ distinct self-reversible codewords. Therefore, all distinct self-reversible codewords form a subspace of dimension $\frac{k+1}{2}$ of $\mathcal{C}$, resulting in a total of $q^{\frac{k+1}{2}}$ self-reversible codewords.
From Cases $A$ and $B$, we can conclude that the total number of self-reversible codewords in code $C$ is $q^{\frac{k}{2}}$.

Conversely, assume that the total number of self-reversible codewords in code $C$ is $q^{\frac{k}{2}}$. Let $U = \{u_1, u_2, \ldots, u_{\frac{k}{2}}\}$ be a linearly independent subset of all self-reversible codewords in $C$. This subset forms a subspace with dimension $\frac{k}{2}$ of $C$. Since $C$ is reversible, every self-reversible codeword of subspace $U$ can be written as $u_i = v_i + \text{Flip}(v_i)$ ($i = 1, 2, \ldots, \frac{k}{2}$). Then, the sets $W_i = \{v_i, \text{Flip}(v_i)\}$, for $i = 1, 2, \ldots, \frac{k}{2}$, span distinct subspaces of dimension 2 of $C$. For each $j$, $W_j \cap \sum_{i<j} W_i = \{0\}$, for $i, j = 1, 2, \ldots, \frac{k}{2}$. Thus, $B = \cup_{i=1}^{\frac{k}{2}} W_i$, it contains $k$ linearly independent codewords, and the direct sum of $W_i$'s forms the basis of $C$, i.e., $B = W_1 \oplus W_2 \oplus \ldots \oplus W_{\frac{k}{2}}$ is a basis of $C$.

**Case B:** Suppose $k$ is odd and the total number of self-reversible codewords in $C$ is $q^{\frac{k-1}{2}}$. Let $t$ be one of the self-reversible codewords in $C$. Therefore, the subset $t$ forms a subspace of dimension 1 of $C$ and it is disjoint from the subspace $t$ in $C$. This subset forms a subspace with dimension $\frac{k-1}{2}$ of $C$. Since $C$ is reversible, every self-reversible codeword of subspace $U$ can be written as $u_i = v_i + \text{Flip}(v_i)$ ($i = 1, 2, \ldots, \frac{k-1}{2}$). Then, the sets $W_i = \{v_i, \text{Flip}(v_i)\}$, for $i = 1, 2, \ldots, \frac{k-1}{2}$, span distinct subspaces of dimension 2 of $C$. For each $j$, $W_j \cap \sum_{i<j} W_i = \{0\}$, for $i, j = 1, 2, \ldots, \frac{k-1}{2}$. Thus, $B = \cup_{i=1}^{\frac{k-1}{2}} W_i$, it contains $k-1$ linearly independent codewords, and the direct sum of $W_i$'s and $t$ forms a basis of $C$, i.e., $B = W_1 \oplus W_2 \oplus \ldots \oplus W_{\frac{k-1}{2}} \oplus t$ is a basis of $C$.

(ii) The proof is similar to that for 3.3(i).

**Example 3.1.** Consider a $[7, 3, 4]$ reversible code $C$ over $GF(3)$ whose generator matrix is given by

$$G = \begin{bmatrix} 1 & 2 & 1 & 0 & 1 & 1 & 2 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 2 & 1 & 1 & 0 & 1 & 2 & 1 \end{bmatrix}.$$  

The total number of self-reversible codewords in $C$ is $q^{\frac{k}{2}} = 9$ as the generators are $(0, 0, 0, 1, 0, 0, 0)$ and $(0, 0, 1, 0, 1, 0, 0)$. It is also to be observed that the generator matrix $G$ above is in the form $[A\mid y\mid A^3]$.

This example follows from Theorem 3.3(i).

**Example 3.2.** Consider a $[6, 4, 2]$ reversible code $C$ over $GF(2)$ whose generator matrix is given by

$$G = \begin{bmatrix} 1 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 1 \end{bmatrix}.$$  

The total number of self-reversible codewords in $C$ is $q^{\frac{k}{2}} = 4$. It is also to be observed that the generator matrix $G$ above is in the form $G = [A\mid A^3]$. This example follows from Theorem 3.3(ii).

**Remark 3.1.** Some of the reversible codes with a generator matrix $G$ cannot be represented in the form $G = [A\mid y\mid A^3]$ or $G = [A\mid A^3]$, because the total number of self-reversible codewords in $C$ is not equal to $q^{\frac{k}{2}}$. This can be seen from the following examples (Examples 3.3 and 3.4).
Example 3.3. The matrix \( G \) given by
\[
G = \begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1
\end{bmatrix}
\]
is a generator matrix for an \([8, 4, 1]\) binary reversible code \( C \) in the RT-metric. However, this generator matrix \( G \) cannot be written in the form of \([A|A^S]\) for any matrix \( A \). It is also to be noted that the total number of self-reversible codewords in \( C \) is 8, which is not equal to \( q^{\lceil k/2 \rceil} = 4 \).

Example 3.4. The matrix \( G \) given by
\[
G = \begin{bmatrix}
1 & 0 & 1 & 0 & 0 \\
0 & 1 & 0 & 2 & 0 \\
0 & 0 & 1 & 0 & 1
\end{bmatrix}
\]
is a generator matrix for a \([5, 3, 3]\) ternary reversible code \( C \) in the RT-metric. However, this generator matrix \( G \) cannot be written in the form of \( G = [A|y|A^S] \) for any matrix \( A \). It is also to be noted that the total number of self-reversible codewords in \( C \) is 3, which is not equal to \( q^{\lceil k/2 \rceil} = 9 \).

Theorem 3.4. Let \( C \) be a self-reversible code of length \( n \) with dimension \( k \) over \( \mathbb{F}_q^n \). Then:
(i) If \( C \) has an odd length \( n \), then we can find a generator matrix of \( C \) in the form \( G = [A|y|\text{Flip}(A)] \), where \( y \) is a column vector, if and only if the total number of self-reversible codewords in \( C \) is \( q^k \).
(ii) If \( C \) has an even length \( n \), then we can find a generator matrix of \( C \) in the form \( G = [A|\text{Flip}(A)] \) if and only if the total number of self-reversible codewords in \( C \) is \( q^k \).

Proof. The proof of this theorem is similar to the proof of Theorem 3.3.

Theorem 3.5. Let \( C \) be an \([n, k, d]_q \) reversible code with the total number of self-reversible codewords \( q^{\lceil k/2 \rceil} \). Then, the dual \( C^\perp \) of \( C \) is an \([n, n-k, d^\perp]_q \) reversible code, with the total number of self-reversible codewords \( q^{\lceil n-k/2 \rceil} \).

Proof. The proof of Theorem 3.5 is straightforward, relying on notations and basic algebraic manipulations.

4. Reversible MDS codes in the RT-metric

Theorem 4.1. Let \( C \) be a code of length \( n \) with dimension \( k \) (where \( k \leq \frac{n}{2} \)) in the RT-metric, whose generator matrix is in the form \( G = [A_k|Y|A_k^S] \), where \( Y \) is a \( k \times (n - 2k) \) matrix. Then, \( C \) is MDS if and only if \( A_k \) is non-singular.

Proof. Suppose that \( C \) is a code of length \( n \) with dimension \( k \) (where \( k \leq \frac{n}{2} \)) in the RT-metric, whose generator matrix is in the form \( G = [A_k|Y|A_k^S] \), where \( Y \) is a \( k \times (n - 2k) \) matrix. Let \( C \) be an MDS code. Assume in contrary that \( A_k \) is singular. Then, \( A_k^S \) is also singular. Consequently, there exist at least two codewords \( x \) and \( z \) in \( C \) with the last \( k \) positions being the same, i.e., \( x = (x_1, x_2, \ldots, x_{n-k}, x_{n-k+1}, \ldots, x_n) \) and \( z = (z_1, z_2, \ldots, z_{n-k}, x_{n-k+1}, \ldots, x_n) \). According to [31], “an \((n, K, d_p)q \) code is MDS if and only if
its partition number is \( n - d_p + 1 \).” Thus, none of the two codewords have the same \((n - d_p + 1)\)-tuple as their last \( n - d_p + 1 \) coordinates, which leads to a contradiction. Hence, \( A_k \) is non-singular.

Conversely, assume that \( A_k \) is non-singular. Then, \((A_k^S)^{-1}\) is also non-singular. Thus, \((A_k^S)^{-1}G\) is a generator matrix of \( C \) in the following form: \((A_k^S)^{-1}G = [(A_k^S)^{-1}A_k[(A_k^S)^{-1}Y](A_k^S)^{-1}A_k^S]\) = \([(A_k^S)^{-1}A_k[(A_k^S)^{-1}Y]I_k]\). Hence, \( C \) is an MDS.

The following examples (Examples 4.1 and 4.2) illustrate Theorem 4.1.

**Example 4.1.** Consider a \([10, 4, 7]\) linear code \( C \) over \( GF(2) \) whose generator matrix is given by

\[
G = \begin{bmatrix}
1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 1 \\
0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 1 & 0 \\
0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 0 \\
1 & 1 & 0 & 0 & 1 & 1 & 0 & 0 & 1 & 0
\end{bmatrix}.
\]

Here, \( d_1 = 7, d_2 = 8, d_3 = 9, \) and \( d_4 = 10 \). It is also to be observed that the generator matrix \( G \) above is in the form \([A_k|Y|A_k^S]\) and that \( A_k \) is invertible.

**Example 4.2.** Consider a \([6, 3, 4]\) reversible code \( C \) over \( GF(3) \) whose generator matrix is given by

\[
G = \begin{bmatrix}
1 & 2 & 1 & 1 & 2 & 2 \\
0 & 0 & 2 & 2 & 0 & 0 \\
2 & 2 & 1 & 1 & 2 & 1
\end{bmatrix}.
\]

Here, \( d_1 = 4, d_2 = 5, \) and \( d_3 = 6 \). It is also to be observed that the generator matrix \( G \) above is in the form \([A_k|Y|A_k^S]\) and that \( A_k \) is invertible.

**Corollary 4.1.** Let \( C \) be a code of length \( n \) with dimension \( k \) (where \( k \le \frac{n}{2} \)) in the RT-metric, whose generator matrix is in the form \( G = [A_k|Y|A_k^S]\), where \( Y \) is a \( k \times (n - 2k) \) matrix. Then, \( C \) is RMDS if and only if \( A_k \) is non-singular and \( Y \) is centrosymmetric.

**Proof.** If we assume that \( C \) is RMDS in the RT-metric, from Theorem 4.1, \( A_k \) is non-singular. It is sufficient to prove that \( Y \) is centrosymmetric. As \( C \) is reversible, from Lemma 3.1, \( G^S \) is also a generator matrix of \( C \). Note that the rows of \( G^S = [A_k|Y^S|A_k^S] \) and those of \( G = [A_k|Y|A_k^S] \) generate the same code \( C \). This implies that \( Y = Y^S \) or \( Y \) is centrosymmetric.

Conversely, assume that \( A_k \) is non-singular and \( Y \) is centrosymmetric. \( G = [A_k|Y|A_k^S] \) is a generator matrix of \( C \), and \((A_k^S)^{-1}G = [(A_k^S)^{-1}A_k[(A_k^S)^{-1}Y](A_k^S)^{-1}A_k^S]\) is a generator matrix of \( C \). This implies that \( G' = [B_k|Y|I_k] \) is a generator matrix of \( C \), where \( B_k = (A_k^S)^{-1}A_k \) and \( Y_1 = (A_k^S)^{-1}Y \). It is sufficient to prove that \( C \) is reversible, that is, to prove \( Y_1 = B_kY_1^S \) and \((\text{Flip}(B_k))^S = B_kB_k^S = B_k^S B_k = I_k \). In [32], Theorem 3 states that the linear code \( C \) is RMDS code in the RT-metric if and only if \( Y_1 = B_kY_1^S \) and \((\text{Flip}(B_k))^S = B_kB_k^S = B_k^S B_k = I_k \). Thus, \( B_k = (A_k^S)^{-1}A_k \) and \( B_k^S = A_k^{-1}R_k^S A_k R_k \).

Consider \( Y_1 = (A_k^S)^{-1}Y^S \) (\( Y \) is centrosymmetric)

\[
= (A_k^S)^{-1}(A_kA_k^S^{-1})(R_k^S\text{Flip}(Y)) = ((A_k^S)^{-1}A_k)(R_k R_k^S A_k^{-1})(R_k \text{Flip}(Y))
\]

\[
= (B_k) R_k R_k R_k^S A_k^{-1}(\text{Flip}(Y)) \quad (\because B_k = (A_k^S)^{-1}A_k)
\]

\[
= (B_k)(R_k(A_k^S)^{-1}(\text{Flip}(Y)))
\]

\[
= B_k Y_1^S \quad (\because Y_1 = (A_k^S)^{-1}Y).
\]
Consider \((\text{Flip}(B_k))^2 = B_k B_k^S\)
\[
= ((A_k^S)^{-1}A_k)(A_k^{-1}R_k^{-1}A_k R_k)
= (R_k A_k R_k)^{-1}(R_k A_k R_k)
= I_k.
\]

The following example (Example 4.3) illustrates Corollary 4.1.

**Example 4.3.** Consider an [11, 4, 8] reversible code \(C\) over \(GF(2)\) whose generator matrix is given by
\[
G = \begin{bmatrix}
1 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 1 & 1 & 0 & 1 & 0 \\
1 & 1 & 0 & 0 & 1 & 1 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 1
\end{bmatrix}.
\]

Here, \(d_1 = 8\), \(d_2 = 9\), \(d_3 = 10\), and \(d_4 = 11\). It is also to be observed that the generator matrix \(G\) above is in the form \([A_k|Y|A_k^S]\). Thus, \(A_k\) is invertible and \(Y\) is centrosymmetric.

**Theorem 4.2.** Let \(C\) be a code of even length \(n\) with dimension \(k\) \((n > k > n/2)\) in the RT-metric, where its generator matrix is in the form \(G = [A|A^S]\), with \(A_k\) representing the first \(k \times k\) square matrix of \(G\). Then, the \(C\) is RMDS if and only if \(A_k\) is non-singular.

**Proof.** The proof is similar to the proof of Theorem 4.1. The following example (Example 4.4) illustrates Theorem 4.2.

**Example 4.4.** Consider a [6, 4, 3] reversible code \(C\) over \(GF(2)\) whose generator matrix is given by
\[
G = \begin{bmatrix}
1 & 0 & 0 & 1 & 1 \\
0 & 1 & 0 & 1 & 0 \\
0 & 1 & 0 & 1 & 0 \\
1 & 1 & 0 & 0 & 0
\end{bmatrix}.
\]

Here, \(d_1 = 3\), \(d_2 = 4\), \(d_3 = 5\), and \(d_4 = 6\). It is also to be observed that the generator matrix \(G\) above is in the form \(G = [A|A^S]\) and that \(A_k\) is invertible.

**Theorem 4.3.** Let \(C\) be a code of odd length \(n\), with dimension \(k\) where \(n > k > n/2\), in the RT-metric. Its generator matrix is in the form \(G = [A|y|A^S]\), where \(A_k\) represents the first \(k \times k\) square matrix of \(G\). Then, the \(C\) is RMDS if and only if \(A_k\) is non-singular and \(y\) is a column centrosymmetric vector.

**Proof.** The proof is similar to the proof of Corollary 4.1. The following example (Example 4.5) illustrates Theorem 4.3.

**Example 4.5.** Consider a [3, 2, 2] reversible code \(C\) over \(GF(5)\) whose generator matrix is given by
\[
G = \begin{bmatrix}
3 & 4 & 0 \\
0 & 4 & 3
\end{bmatrix}.
\]

Here, \(d_1 = 2\) and \(d_2 = 3\). It is also to be observed that the generator matrix \(G\) above is in the form \(G = [A|y|A^S]\) and that \(A_k\) is invertible.
Theorem 4.4. Every self-reversible \([n = 2k, k, d_\rho]\) code \(C\) in the RT-metric is MDS.

Proof. Let \(C\) be any self-reversible \([n = 2k, k, d_\rho]\) code with even length \(n = 2k\). Then, by using Definition 3 in [27], there exists a partition number \(l = k\) such that \(C\) is of type \((k + 1, k + 2, \ldots, 2k)\). Hence, \(C\) is MDS. The following example (Example 4.6) illustrates Theorem 4.4.

Example 4.6. Consider a \([6, 3, 4]\) reversible code \(C\) over \(GF(2)\) whose generator matrix is given by

\[
G = \begin{bmatrix}
0 & 0 & 1 & 1 & 0 & 0 \\
0 & 1 & 0 & 0 & 1 & 0 \\
1 & 0 & 0 & 0 & 0 & 1
\end{bmatrix}.
\]

Here, \(d_1 = 4\), \(d_2 = 5\), and \(d_3 = 6\). It is also to be observed that the generator matrix \(G\) above is in the form \(G = [A_k|\text{Flip}(A_k)]\) and that \(A_k\) is invertible.

Theorem 4.5. Every self-reversible \([n = 2k - 1, k, d_\rho]\) code \(C\) with odd length \(n = 2k - 1\) in the RT-metric is MDS.

Proof. The proof of this theorem is similar to the proof of Theorem 4.4. The following example (Example 4.7) illustrates Theorem 4.5.

Example 4.7. Consider a \([5, 3, 3]\) reversible code \(C\) over \(GF(3)\) whose generator matrix is given by

\[
G = \begin{bmatrix}
0 & 0 & 2 & 0 & 0 \\
0 & 1 & 0 & 1 & 0 \\
2 & 0 & 0 & 0 & 2
\end{bmatrix}.
\]

Here, \(d_1 = 4\), \(d_2 = 5\), and \(d_3 = 6\). It is also to be observed that the generator matrix \(G\) above is in the form \(G = [A|\text{Flip}(A)]\) and that \(A_k\) is invertible.

5. Self-dual reversible codes in the RT-metric

Theorem 5.1. If \(C\) is an \([n = 2k, k, d_\rho]\) reversible code over \(\mathbb{F}_q\) in the RT-metric with a minimum distance \(d_\rho = 1\), then \(C\) cannot be self-dual in the RT-metric.

Proof. The proof of Theorem 5.1 is straightforward, relying on notations and basic algebraic manipulations.

Remark 5.1. If \(C\) is an \([n = 2k, k, d_\rho]\) self-dual code over \(\mathbb{F}_q\) in the RT-metric with a minimum distance of \(d_\rho = 1\), then \(C\) cannot be reversible. This can be seen from the following examples (Examples 5.1 and 5.2).

Example 5.1. Consider a \([6, 3, 1]\) linear code \(C\) over \(GF(2)\) whose generator matrix is given by

\[
G = \begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 1 & 0 & 0 & 0 \\
0 & 1 & 0 & 1 & 1 & 0
\end{bmatrix}.
\]

Here, \(d_1 = 1\), \(d_2 = 3\), and \(d_3 = 5\). It can be observed that \(C\) is a \([6, 3, 1]\) self-dual code in the RT-metric over \(GF(2)\), but it is not reversible.
Example 5.2. Consider a [4, 2, 1] linear code $C$ over $GF(5)$ whose generator matrix is given by

$$G = \begin{bmatrix} 4 & 0 & 0 & 0 \\ 2 & 0 & 3 & 0 \end{bmatrix}. $$

Here, $d_1 = 1$ and $d_2 = 3$. It can be observed that $C$ is a [4, 2, 1] self-dual code in the RT-metric over $GF(5)$, but it is not reversible.

Theorem 5.2. Let $C$ be an $[n = 2k, k, d_p]$ binary reversible code in the RT-metric, with a generator matrix in the form $[A_k|A_S^k]$. Then, $C$ is self-dual if and only if it satisfies one of the following conditions:

(i) $A_k\text{Flip}(A_S^k)^T = (A_k\text{Flip}(A_S^k))^T$;
(ii) $\text{Flip}(A_k A_k^T)$ is symmetric;
(iii) $A_k A_k^T$ is centrosymmetric.

Proof. Consider:

(i) Suppose $C$ is self-dual [29], which implies that

$$GG^\diamond = 0$$

$$\iff [A_k|A_S^k][\frac{(\text{Flip}(A_S^k))^T}{\text{Flip}(A_k)^T}] = 0$$

$$\iff A_k(\text{Flip}(A_S^k))^T + A_S^k(\text{Flip}(A_k))^T = 0$$

$$\iff R_k A_k A_k^T + A_k \text{Flip}(A_S^k) = 0$$

$$\iff R_k A_k A_k^T = A_k \text{Flip}(A_S^k)$$

$$\iff A_k \text{Flip}(A_k^T R_k) = (A_k \text{Flip}(A_k^T))^T.$$

(ii) Consider

$$(A_k A_k^T) R_k = (A_k \text{Flip}(A_k^T))^T$$

$$\iff \text{Flip}(A_k A_k^T) = (A_k A_k^T R_k)^T$$

$$\iff \text{Flip}(A_k A_k^T) = (\text{Flip}(A_k A_k^T))^T$$

$$\iff \text{Flip}(A_k A_k^T)$$ is symmetric.

(iii) Consider

$$R_k A_k A_k^T = A_k \text{Flip}(A_k^T)$$

$$\iff R_k A_k A_k^T = A_k A_k^T R_k$$

$$\iff R_k (A_k A_k^T) = (A_k A_k^T) R_k$$

$$\iff (A_k A_k^T)$$ is centrosymmetric.

Example 5.3. Consider a [6, 3, 3] reversible code $C$ over $GF(2)$ whose generator matrix is given by

$$G = \begin{bmatrix} 1 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 1 \end{bmatrix}.$$  

Here, $d_1 = 3$, $d_2 = 5$, and $d_3 = 6$. It is also to be observed that the generator matrix $G$ above is in the form $G = [A_k|A_S^k]$ and that $\text{Flip}(A_k A_k^T)$ is symmetric.
Theorem 5.3. Let $C$ be an $[n = 2k, d_1, d_2]$ non-binary reversible code in the RT-metric, with a generator matrix in the form $[A_k|A^S_k]$. Then, $C$ is self-dual if and only if it satisfies one of the following conditions:

(i) $A_k\text{Flip}(A^T_k) = -(A_k\text{Flip}(A^T_k))^T$;

(ii) $\text{Flip}(A_kA^T_k)$ is skew-symmetric.

Proof. The proof of this theorem is similar to the proof of 5.2.

Example 5.4. Consider a $[4, 2, 3]$ reversible code $C$ over $GF(5)$ whose generator matrix is given by

$$G = \begin{bmatrix} 4 & 0 & 3 & 0 \\ 0 & 3 & 0 & 4 \end{bmatrix}.$$  

Here, $d_1 = 3$ and $d_2 = 4$. It is also to be observed that the generator matrix $G$ above is in the form $G = [A_k|A^S_k]$ and that $\text{Flip}(A_kA^T_k)$ is skew-symmetric.

Theorem 5.4. Every binary self-reversible $[n = 2k, d_1, d_2]$ code $C$ in the RT-metric is SR-MDS.

Proof. The proof of Theorem 5.4 is straightforward, relying on notations and basic algebraic manipulations.

Example 5.5. Consider a $[4, 2, 3]$ binary self-reversible code $C$ over $GF(2)$ whose generator matrix is given by

$$G = \begin{bmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 \end{bmatrix}.$$  

Here, $d_1 = 3$ and $d_2 = 4$. It is also to be observed that the generator matrix $G$ above is in the form $G = [A_k|\text{Flip}(A_k)]$, and that $C$ is self-dual.

6. Some constructions of reversible codes in the RT-metric

Theorem 6.1. Let $G$ be a generator matrix of a self-dual code of length $n$. Then,

$$\begin{bmatrix} G & O_{n/2,n} \\ O_{n/2,n} & \text{Flip}(G) \end{bmatrix}$$

generates an SR code of length $2n$ in the RT-metric.

Theorem 6.2. Let $C$ be an $[n_1, k, d, R]$ RMDS code with a generator matrix in the form $[A^S|A]$ in the RT-metric. Then,

$$\begin{bmatrix} O & R_{n_2} & I_{n_2} & O \\ A^S & O & O & A \end{bmatrix}$$

generates an RMDS code $[2(n_1 + n_2), n_1 + n_2, d, d + R + n_2]$ with covering radius $R + n$.

Proof. Consider

$$\begin{bmatrix} O & R_{n_2} & I_{n_2} & O \\ A^S & O & O & A \end{bmatrix} \begin{bmatrix} O & \text{Flip}(A)^T \\ R_{n_2} & O \\ I_{n_2} & O \\ O & \text{Flip}(A^S)^T \end{bmatrix}$$

$$= 2I_{n_2}$$

$$= O \text{ (if } C \text{ is binary self-dual).}$$
7. Conclusions

In this study, we provided some basic properties of reversible linear codes and obtained a condition for a reversible code to be an MDS code. Furthermore, we established some necessary and sufficient conditions for a reversible code to be self-dual. Finally, some constructions of reversible codes in the RT-metric were proposed.

Author contributions

Conceptualization: Bodigiri Sai Gopinadh formulated the initial research problem and developed the overarching mathematical framework. Validation: Venkatrajam Marka independently verified the correctness of the mathematical results, played a pivotal role in problem discussion, and providing continuous supervision. Both authors have read and approved the final version of the manuscript for publication.
